UML Use Case Extend

Extend is a **directed relationship** that specifies how and when the behavior defined in usually supplementary (optional) **extending use case** can be inserted into the **behavior** defined in the **extended use case**.

Extended use case is meaningful on its own, it is **independent** of the extending use case. **Extending** use case typically defines **optional behavior** that is not necessarily meaningful by itself. The extend relationship is **owned** by the extending use case. The same extending use case can extend more than one use case, and extending use case may itself be extended.

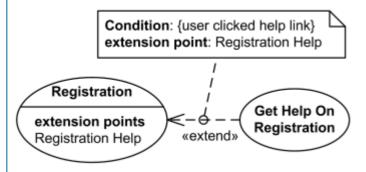

The extension takes place at one or more **extension points** defined in the **extended use case**.

Extend relationship is shown as a dashed line with an open arrowhead directed from the **extending use case** to the **extended (base) use case**. The arrow is labeled with the keyword **extend**.

Registration use case is complete and meaningful on its own. It could be extended with optional **Get Help On Registration** use case.

The **condition** of the extend relationship as well as the references to the **extension points** are optionally shown in a **comment** note attached to the corresponding extend relationship.

Registration use case is conditionally extended by Get Help On Registration use case in extension point Registration Help.

Extension Point

An **extension point** is a **feature** of a **use case** which identifies (references) a point in the behavior of the use case where that behavior can be extended by some other (extending) use case, as specified by **extend** relationship.

UML use case extend relationship is used to show how and when some optional extending use case can be inserted into extended (base) use case.

Extension points may be shown in a compartment of the use case oval symbol under the heading **extension points**. Each extension point must have a **name**, unique within a use case. Extension points are shown as a text string according to the syntax:

extension point ::= name [: explanation]

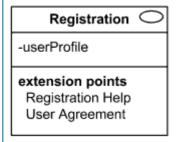

The optional *explanation* is some description usually given as informal text. It could be in other forms, such as the name of a **state** in a state machine, an activity in an activity diagram, some precondition or postcondition.

User Agreement

Registration **use case** with **extension points** Registration Help and User Agreement

Extension points may be shown in a compartment of the use case rectangle with **ellipse icon** under the heading **extension points**.

Extension points of the Registration **use case**, shown using the rectangle notation

UML Use Case Include

Use case include is a directed relationship between two use cases which is used to show that behavior of the included use case (the addition) is inserted into the behavior of the including (the base) use case.

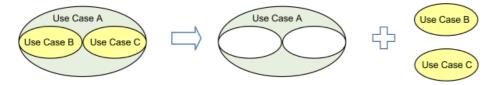

The **include** relationship could be used:

- · to simplify large use case by splitting it into several use cases,
- to extract common parts of the behaviors of two or more use cases.

A large use case could have some behaviors which might be detached into distinct smaller use cases to be included back into the base use case using the UML **include** relationship. The purpose of this action is modularization of behaviors, making them more manageable.

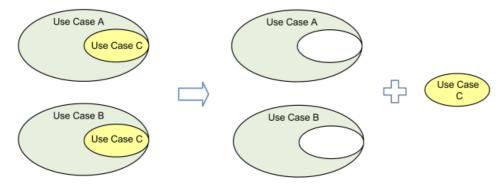

Use case B is extracted from larger use case A into a separate use case.

Use cases B and C are extracted from larger use case A into separate use cases.

When two or more use cases have some **common behavior**, this common part could be extracted into a separate use case to be included back by the use cases with the UML **include** relationship.

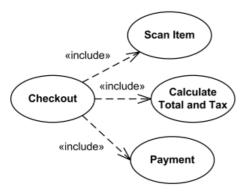

Use case C is extracted from use cases A and B to be reused by both use cases using UML include relationship.

Execution of the included use case is analogous to a subroutine call or macro command in programming. All of the behavior of the included use case is executed at a **single location** in the including use case before execution of the including use case is resumed.

Note, while UML 2.x defines **extension points** for the **extend** relationship, there are no "inclusion points" to specify location or condition of inclusion for the **include**.

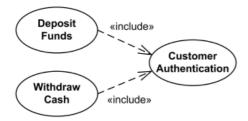

Including use case depends on the addition of the included use case, which is required and not optional. It means that including use case is **not complete** by itself, and so it would make sense to refer to the including use cases as **abstract use cases**. Neither of **UML 2.x** specifications up to the **UML 2.5** even mentions **abstract use cases**. A number of other UML sources define abstract use case as including use case, while in fact it has to be the other way around: including use case is abstract use case. See discussion of the definition of **abstract use cases**.

Include relationship between use cases is shown by a dashed arrow with an open arrowhead from the including (base) use case to the included (common part) use case. The arrow is labeled with the keyword «include».

Checkout use case includes several use cases - Scan Item, Calculate Total and Tax, and Payment

Large and complex Checkout use case has several use cases extracted, each smaller use case describing some logical unit of behavior. Note, that including Checkout use case becomes incomplete by itself and requires included use cases to be complete.

Deposit Funds and **Withdraw Cash** use cases include **Customer Authentication** use case.

Use Case Relationships Compared

This site received many requests related to which use case relationship should be used in which situation. I combined several key points from UML 2.4 Specification into the table below. Also, take a look at related discussion in the next paragraph.

Generalization	Extend	Include
Bank ATM Transaction Withdraw Cash	Bank ATM rransaction (extend) Help	Bank ATM
Base use case could be abstract use case (incomplete) or concrete (complete).	Base use case is complete (concrete) by itself, defined independently.	Base use case is incomplete (abstract use case).
Specialized use case is required, not optional, if base use case is abstract.	Extending use case is optional, supplementary.	Included use case required, not optional.
No explicit location to use specialization.	Has at least one explicit extension location.	No explicit inclusion location but is included at some location.
No explicit condition to use specialization.	Could have optional extension condition.	No explicit inclusion condition.

Missing Use Case Relationship

I was baffled while creating some use case diagrams and answering some questions of this website users, all with a similar problem and no obvious solution using **UML 2.4**. One quite seemingly simple but insolvable example is to specify relationships between **Payment**, **Payment by Credit**, **Payment by Cash**, etc. use cases when we want to allow customers to pay partially by cash, partially by credit, etc. This is quite common situation for POS terminal checkout in supermarkets. (Another similar example is **Plan Trip** and **Find Flight**, **Find Hotel**, **Find Car**, etc. where user might want to search not just for one but for several things at a time.)

Though use case **generalization** seems natural for **Payment**, **Payment by Credit**, **Payment by Check**, etc., but we can't use it because it suggests using **only one** specific form of payment at a time.

Extend seems appropriate because it has extension points with extension conditions, but we can't use it because the base use case **Payment** must be **complete** by itself, which is obviously not the case that we have.

Include seems fine because the base use case Payment is not complete by itself and all different kinds of payments supplement it, but we can't use it because for

UML use case include relationship shows that behavior of the included use case is inserted into the behavior of the including use case.

include relationship included case is not optional but **required** (and there is no inclusion condition), which means that customer will have to pay using **all** methods of payment - which is dead wrong.

My hope is that they update the **include** relationship to allow inclusion conditions and locations the similar way as it was done for **extend**, or at least provide more use case diagram examples in the future versions of UML specification.
